

The UniBow bowsprit is a universal system that can be installed on all models of sailboats.

In order to determine the protrusion that is obtained after installation and the width of the anchor roller plate, we need to know some measurements of the boat on which it is installed.

If we have already installed UniBow on the same boat model, these measures are not needed, contact the technical office to find out our boat database.

To take the measurements it is necessary to determine two sections of the bow S1 and S2.

These sections should be determined a maximum of one meter from the bow, where it is easier to take measurements.

If it is possible to accurately detect the angle A° , the measurements relating to sections S1 and S2 may not be taken.

UniBow has been designed to allow a minimum margin of error in the measurements, naturally the greater the accuracy of the measurements, the better the result after installation.

For any clarification on the measures, you can contact our technical office by email.
